(a) Train a monitor in the browser: held-out accuracy, catch rate, limits

0.986
AUROC on tasks held out in cross-validation (95% CI 0.981–0.991, bootstrap over tasks)

28.6%
of violations escalated when 5.0% of all steps go to review (the most this budget allows is 28.6%: violations are 17.5% of your steps)

100.00%
of escalated steps are real violations (0.0% of safe steps escalated)

1,500 steps, 262 violations, 660 task groups, 5-fold grouped cross-validation. Regularisation chosen by cross-validation: C = 10 (AUROC by C: 0.1: 0.958, 1: 0.979, 10: 0.986). Vocabulary: 8,397 context terms, 1,687 action terms.

How far to trust these numbers. Cross-validation holds out whole task groups. Thus it estimates the performance on new tasks *of the same type*. It does not cover a new policy, new tools or a different benchmark. In our tests, we removed one policy family from the training data. The catch rate for that family at a 5% budget fell from 88% to 0%. With 20 to 40 labelled steps of that policy, it came back to 85–94%.

By tool

Tool	Steps	Violations	Escalated at the budget
`execute_mock_command`	705	165	50/165

(b) A closed agent's actions in the monitor's space, with the revie
